***Carbocyclic and Heterocyclic Substituted Semicarbazones and

Background of the Invention

5

Field of the Invention

This invention is in the field of medicinal chemistry. In particular, the invention relates to carbocyclic and heterocyclic substituted semicarbazones and thiosemicarbazones, and the discovery that these compounds act as blockers of sodium (Na^+) channels.

Related Art

15

20

Several classes of therapeutically useful drugs, including local anesthetics such as lidocaine and bupivacaine, antiarrhythmics such as propafenone and amiodarone, and anticonvulsants such as lamotrigine, phenytoin and carbamazepine, have been shown to share a common mechanism of action by blocking or modulating Na^+ channel activity (Catterall, W.A., *Trends Pharmacol. Sci.* 8:57-65 (1987)). Each of these agents is believed to act by interfering with the rapid influx of Na^+ ions.

25

Recently, other Na^+ channel blockers such as BW619C89 and lifarizine have been shown to be neuroprotective in animal models of global and focal ischemia and are presently in clinical trials (Graham *et al.*, *J. Pharmacol. Exp. Ther.* 269:854-859 (1994); Brown *et al.*, *British J. Pharmacol.* 115:1425-1432 (1995); *SCRIP* 1870:8 (1993); *SCRIP* 1773:14 (1992)).

30

35

The neuroprotective activity of Na^+ channel blockers is due to their effectiveness in decreasing extracellular glutamate concentration during ischemia by inhibiting the release of this excitotoxic amino acid neurotransmitter. Studies have shown that unlike glutamate receptor antagonists, Na^+ channel blockers prevent hypoxic damage to mammalian white matter (Stys *et al.*, *J. Neurosci.* 12:430-439 (1992)). Thus, they may offer advantages for treating certain types of strokes or neuronal trauma where damage to white matter tracts is prominent. In addition to playing a major role in neurotoxicity involving stroke, glutamate is also a key neurotransmitter which mediates otoneurotoxicity resulting in acute or progressive hearing loss and tinnitus (Pujol *et al.* *Acta Otolaryngol (stockh)* 113:330-334 (1993).

- 2 -

Therefore, Na⁺ channel blockers are expected to be effective in preventing and treating otoneurotoxicity by decreasing extracellular glutamate concentration. Similarly, Na⁺ channel blockers will be useful for preventing and treating eye diseases involving excitatory toxicity such as glaucoma and CMV retinitis.

Another example of clinical use of a Na⁺ channel blocker is riluzole. This drug has been shown to prolong survival in a subset of patients with ALS (Bensimm *et al.*, *New Engl. J. Med.* 330:585-591 (1994)) and has subsequently been approved by the FDA for the treatment of ALS. In addition to the above-mentioned clinical uses, carbamazepine, lidocaine and phenytoin are occasionally used to treat neuropathic pain, such as from trigeminal neurologia, diabetic neuropathy and other forms of nerve damage (Taylor and Meldrum, *Trends Pharmacol. Sci.* 16:309-316 (1995)), and carbamazepine and lamotrigine have been used for the treatment of manic depression (Denicott *et al.*, *J. Clin. Psychiatry* 55: 70-76 (1994)).

It has been established that there are at least five to six sites on the voltage-sensitive Na⁺ channels which bind neurotoxins specifically (Catterall, W.A., *Science* 242:50-61 (1988)). Studies have further revealed that therapeutic antiarrhythmics, anticonvulsants and local anesthetics whose actions are mediated by Na⁺ channels, exert their action by interacting with the intracellular side of the Na⁺ channel and allosterically inhibiting interaction with neurotoxin receptor site 2 (Catterall, W.A., *Ann. Rev. Pharmacol. Toxicol.* 10:15-43 (1980)).

The compounds of the present invention were assessed by electrophysiological assays in dissociated hippocampal neurons for sodium channel blocker activity. These compounds also could be assayed for binding to the neuronal voltage-dependent sodium channel using rat forebrain membranes and [3H]BTX-B.

15

Sodium channels are large transmembrane proteins that are expressed in various tissues. They are voltage sensitive channels and are responsible for the rapid increase of Na^+ permeability in response to depolarization associated

- 25 -

with the action potential in many excitable cells including muscle, nerve and cardiac cells.

One aspect of the present invention is the discovery of the mechanism of action of the compounds herein described as specific Na⁺ channel blockers.

5 In one aspect of the present invention it has been discovered that compounds disclosed in International published applications WO 94/06758 and WO 96/40628 are specific Na⁺ channel blockers. Based upon the discovery of this mechanism, these compounds, as well as novel compounds described herein, are contemplated to be useful in treating or preventing neuronal loss due to
10 focal or global ischemia, and in treating or preventing neurodegenerative disorders including ALS, anxiety, and epilepsy. They are also useful in treating or preventing otoneurotoxicity including acute and progressive hearing loss and tinnitus. They are also expected to be effective in treating, preventing or ameliorating neuropathic pain, surgical pain and chronic pain.
15 The compounds are also expected to be useful as antiarrhythmics, anesthetics and antimanic depressants.

The present invention is directed to compounds of Formulae I and VI that are blockers of voltage-sensitive sodium channels. According to the present invention, those compounds having preferred sodium channel blocking
20 properties exhibit an IC₅₀ of about 100 μM or less in the electrophysiological assay described herein. Preferably, the compounds of the present invention exhibit an IC₅₀ of 10 μM or less. Most preferably, the compounds of the present invention exhibit an IC₅₀ of about 1.0 μM or less. Substituted semicarbazones disclosed in WO 94/06758 and WO 96/40628, as well as
25 novel compounds of the present invention, may be tested for their Na⁺ channel blocking activity by the following electrophysiological and binding assays.

Electrophysiological Assay:

30 *Cell preparation:* Acute cultures of rat hippocampal neurons were prepared daily using a modification of procedures described previously (Kuo and Bean, *Mol. Pharm.* 46:716-725 (1994)). Briefly, hippocampi were isolated from 3-11 day old rat pup brains (Sprague-Dawley; Charles River) and were sectioned, by hand, into 0.5 - 1 mm thick transverse slices
35 (Whittemore and Koerner, *Eur. J. Pharm.* 192:435-438 (1991)). Slices were incubated for at least 30 min at room temperature (20 - 24 °C) in an

- 26 -

oxygenated medium (124 mM NaCl, 3.3 mM KCl, 2.4 mM MgSO₄, 2.5 mM CaCl₂, 1.2 mM KH₂PO₄, 26 mM NaHCO₃, pH = 7.4) continuously bubbled with 5% CO₂ / 95 % O₂. Prior to recording, 4-5 slices were transferred to an oxygenated dissociation medium (82 mM NaSO₄, 30 mM K₂SO₄, 3 mM MgCl₂, 2 mM HEPES, 26 mM NaHCO₃, 0.001% phenol red, pH = 7.4) containing 3 mg / mL protease XXIII (Sigma, St. Louis, MO) and incubated for 10 - 15 min at 37°C, while continuously bubbling with 5 % CO₂ / 95 % O₂. Enzymatic digestion was terminated by transferring the slices to dissociation medium without bicarbonate, supplemented with 1 mg / mL bovine serum albumin and 1 mg / mL trypsin inhibitor (Sigma, St. Louis, MO). Slices were then transferred to a 35 mm culture dish containing dissociation medium without bicarbonate, and triturized with a fire-polished glass Pasteur pipette to release single cells. Cells were allowed to settle in this dish for ~30 minutes and were then used for making electrical recordings.

Patch-clamp recordings of voltage-sensitive Na⁺ currents: Whole-cell voltage-clamp recordings were made using conventional patch-clamp technique (Hamill *et al.*, *Pfluegers Arch.* 391:85-100 (1981)) with an Axopatch 200A amplifier (Axon Instruments, Foster City, CA). Recordings were made within 2-3 hours after neuron dissociation. The recording chamber was continuously superfused with Tyrode's solution (156 mM NaCl, 3.5 mM KCl, 2 mM CaCl₂, 5 mM NaHCO₃, 10 mM HEPES, 10 mM glucose, pH 7.4) at a speed of about 1 ml/min. Thin-walled pipettes were pulled from 100- μ l Clay Adams Accu-Fill 90 Micropet disposable pipettes (Becton, Dickenson and Company, Parsipanny, NJ), fire-polished and sylgarded (Dow-Corning, Midland, MI). The pipette resistances ranged from 1 to 3 M Ω when the pipettes were filled with internal solution containing (in mM): 130 CsF, 20 NaCl, 1 CaCl₂, 2 MgCl₂, 10 EGTA, 10 HEPES, pH adjusted to 7.4 with CsOH. Drugs and intervening wash-outs were applied through a linear array of flow pipes (Drummond Microcaps, 2- μ l, 64-mm length). Compounds are dissolved in dimethylsulfoxide (DMSO) to make a 10 mM stock solution, which was subsequently diluted into Tyrode's solution to give final concentrations of 0.1-20 μ M. At the highest (1%) concentration, DMSO inhibited the size of Na⁺ current only slightly. Currents were recorded at room temperature (22-25°C), filtered at 5 kHz with 4-pole Bessel filter, digitized at 20-50- μ s intervals, and stored using Digidata 1200 analog/digital interface with Pclamp6/Clampex software (Axon Instruments). Residual series

- 27 -

resistance ranged from 0.4 to 0.8 MΩ after partial compensation (typically ~90%). The inhibitory potency of drugs was assessed by measuring reductions in the peak amplitude of Na⁺ currents induced by increasing concentrations of compounds tested. Na⁺ currents were elicited by stepping
5 membrane voltage from holding potentials over the range -100 mV to -50 mV, to a pulse potential of -10 mV. The test pulse duration was 5-10 msec, repeated at a frequency ≤ 1 Hz. Concentration-inhibition curves were fitted with equation 1:

10
$$I/I_{\text{control}} = 1/(1 + ([\text{compound}]/IC_{50}))$$
 Eq. 1

where I_{control} is the maximal Na⁺ current in the absence of antagonist, [compound] is the drug concentration, and IC_{50} is the concentration of compound that produces half maximal inhibition.

15 ***Binding Assay:***

The ability of compounds of the present invention to modulate either site 1 or site 2 of the Na⁺ channel was determined following the procedures
20 fully described in Yasushi, *J. Biol. Chem.* 261:6149-6152 (1986) and Creveling, *Mol. Pharmacol.* 23:350-358 (1983), respectively. Rat forebrain membranes were used as sources of Na⁺ channel proteins. The binding assays were conducted in 130 (M choline chloride at 37°C for 60-minute incubation with [³H] saxitoxin and [³H] batrachotoxin as radioligands for site 1 and site 2,
25 respectively.

30 The compounds may be tested for their neuroprotective activity after focal and global ischemia produced in rats or gerbils according to the procedures described in Buchan *et al.* (*Stroke*, Suppl. 148-152 (1993)) and Sheardown *et al.* (*Eur. J. Pharmacol.* 236:347-353 (1993)) and Graham *et al.* (*J. Pharmacol. Exp. Therap.* 276:1-4 (1996)).

35 The compounds may be tested for their neuroprotective activity after traumatic spinal cord injury according to the procedures described in Wrathall

- 28 -

et. al. (Exp. Neurology 137:119-126 (1996)) and Iwasaki et. al. (J. Neuro Sci. 134:21-25 (1995)).

35 Also included within the scope of the present invention are the non-toxic pharmaceutically acceptable salts of the compounds of the present invention. Acid addition salts are formed by mixing a solution of the

- 29 -

particular semicarbazones of the present invention with a solution of a pharmaceutically acceptable non-toxic acid such as hydrochloric acid, fumaric acid, maleic acid, succinic acid, acetic acid, citric acid, tartaric acid, carbonic acid, phosphoric acid, oxalic acid, dichloroacetic acid, and the like. Basic salts
5 are formed by mixing a solution of the particular semicarbazones of the present invention with a solution of a pharmaceutically acceptable non-toxic base such as sodium hydroxide, potassium hydroxide, choline hydroxide, sodium carbonate and the like.

The pharmaceutical compositions of the invention may be
10 administered to any animal which may experience the beneficial effects of the compounds of the invention. Foremost among such animals are mammals, e.g., humans, although the invention is not intended to be so limited.

The pharmaceutical compositions of the present invention may be administered by any means that achieve their intended purpose. For example,
15 administration may be by parenteral, subcutaneous, intravenous, intramuscular, intraperitoneal, transdermal, or buccal routes. Alternatively, or concurrently, administration may be by the oral route. The dosage administered will be dependent upon the age, health, and weight of the recipient, kind of concurrent treatment, if any, frequency of treatment, and the
20 nature of the effect desired.

The pharmaceutical preparations of the present invention are manufactured in a manner which is itself known, for example, by means of conventional mixing, granulating, dragee-making, dissolving, or lyophilizing processes. Thus, pharmaceutical preparations for oral use can be obtained by
25 combining the active compounds with solid excipients, optionally grinding the resulting mixture and processing the mixture of granules, after adding suitable auxiliaries, if desired or necessary, to obtain tablets or dragee cores.

Suitable excipients are, in particular, fillers such as saccharides, for example lactose or sucrose, mannitol or sorbitol, cellulose preparations and/or
30 calcium phosphates, for example tricalcium phosphate or calcium hydrogen phosphate, as well as binders such as starch paste, using, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, tragacanth, methyl cellulose, hydroxypropylmethylcellulose, sodium carboxymethylcellulose, and/or polyvinyl pyrrolidone. If desired, disintegrating agents may be added
35 such as the above-mentioned starches and also carboxymethyl-starch, cross-linked polyvinyl pyrrolidone, agar, or alginic acid or a salt thereof, such as

- 30 -

sodium alginate. Auxiliaries are, above all, flow-regulating agents and lubricants, for example, silica, talc, stearic acid or salts thereof, such as magnesium stearate or calcium stearate, and/or polyethylene glycol. Dragee cores are provided with suitable coatings which, if desired, are resistant to gastric juices. For this purpose, concentrated saccharide solutions may be used, which may optionally contain gum arabic, talc, polyvinyl pyrrolidone, polyethylene glycol and/or titanium dioxide, lacquer solutions and suitable organic solvents or solvent mixtures. In order to produce coatings resistant to gastric juices, solutions of suitable cellulose preparations such as acetylcellulose phthalate or hydroxypropymethyl-cellulose phthalate, are used. Dye stuffs or pigments may be added to the tablets or dragee coatings, for example, for identification or in order to characterize combinations of active compound doses.

Other pharmaceutical preparations which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer such as glycerol or sorbitol. The push-fit capsules can contain the active compounds in the form of granules which may be mixed with fillers such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active compounds are preferably dissolved or suspended in suitable liquids, such as fatty oils, or liquid paraffin. In addition, stabilizers may be added.

Possible pharmaceutical preparations which can be used rectally include, for example, suppositories, which consist of a combination of one or more of the active compounds with a suppository base. Suitable suppository bases are, for example, natural or synthetic triglycerides, or paraffin hydrocarbons. In addition, it is also possible to use gelatin rectal capsules which consist of a combination of the active compounds with a base. Possible base materials include, for example, liquid triglycerides, polyethylene glycols, or paraffin hydrocarbons.

Suitable formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form, for example, water-soluble salts and alkaline solutions. In addition, suspensions of the active compounds as appropriate oily injection suspensions may be administered. Suitable lipophilic solvents or vehicles include fatty oils, for example, sesame oil, or synthetic fatty acid esters, for example, ethyl oleate or triglycerides or polyethylene glycol-400 (the compounds are soluble in PEG-400). Aqueous

injection suspensions may contain substances which increase the viscosity of the suspension include, for example, sodium carboxymethyl cellulose, sorbitol, and/or dextran. Optionally, the suspension may also contain stabilizers.

The following examples are illustrative, but not limiting, of the method and compositions of the present invention. Other suitable modifications and adaptations of the variety of conditions and parameters normally encountered in clinical therapy and which are obvious to those skilled in the art are within the spirit and scope of the invention.

4-(4-Fluorophenoxy)benzaldehyde semicarbazone as Na⁺ channel blocker

35 4-(4-Fluorophenoxy)benzaldehyde semicarbazone was tested in the electrophysiological and binding assays described above and produced dose-dependent inhibition of voltage-gated Na⁺ currents recorded in acutely dissociated rat hippocampal neurons. The blocking effect of this compound on Na⁺ currents was highly sensitive to the holding voltage. For example, at concentrations between 0.1 - 10 μM, 4-(4-fluorophenoxy)benzaldehyde semicarbazone had very little effect on Na⁺ currents activated from a holding membrane voltage of -100 mV, but inhibited currents with increasing potency as the holding potential was progressively depolarized.

- 59 -

Table 1 presents the IC_{50} values derived from concentration-inhibition curves for the captioned compound taken at different holding voltages. The most potent block in these studies was seen at a membrane holding voltage of -60 mV. At this holding voltage the Na^+ current was decreased by 65% as compared to currents elicited from a holding voltage of -100 mV. The decrease in current was due to steady-state inactivation of the Na^+ channels. There was a direct correlation between inhibitory potency of the captioned compound and the degree of Na^+ channel inactivation (Table 1): the higher the degree of inactivation the higher the potency of antagonism. 4-(4-Fluorophenoxy)benzaldehyde semicarbazone appeared to have little effect on the overall shape of the Na^+ channel current-voltage relationship measured at peak current.

This data indicates that 4-(4-fluorophenoxy)benzaldehyde semicarbazone binds to voltage-sensitive Na^+ channels in their inactivated states and has weak potency towards Na^+ channels in their resting states (Ragsdale *et al.*, *Mol. Pharmacol.* 40:756-765 (1991); Kuo and Bean, *Mol. Pharmacol.* 46:716-725 (1994)). The apparent antagonist dissociation constant (K_d) of this compound for inactivated Na^+ channels is $\sim 0.6 \mu M$.

Antinociceptive activity of 4-(4-Fluorophenoxy)benzaldehyde semicarbazone

Analgesic activity of 4-(4-fluorophenoxy)benzaldehyde semicarbazone was assessed in the formalin test. The method of Hunskaar, *et al.*, *J. Neurosci. Method* 14:69-76 (1985), was used with some modifications as described in the following.

10

15

20

Mice were placed in Plexiglas jars for at least 1 h to accommodate to experimental conditions. Following the accommodation period, mice were weighed and injected with 4-(4-Fluorophenoxy)benzaldehyde semicarbazone by i.p. or p.o. administration. Control mice were injected with saline (10 ml/kg). Fifteen min (i.p.) or 30 min (p.o.) following 4-(4-fluorophenoxy)benzaldehyde semicarbazone administration mice were injected with formalin (20 ml of 5% formaldehyde solution in saline) into the dorsal surface of the right hand paw. Mice were immediately transferred to the Plexiglas jars and the amount of time that each mouse spent licking and/or biting the injected paw was recorded for every 5-min period over the 1 h observation period. The data presented here are at 0-5 min (early phase) and from 5-60 min (late phase) following formalin injections. The late phase of the formalin test is the average of eleven 5-min periods.

- 61 -

The result of this test are shown in Figure 1. The antinociceptive activity of 4-(4-fluorophenoxy)benzaldehyde semicarbazone is demonstrated. The compound has a potency of ED₅₀ about 5-10 mg/kg by both routes of administration.

Example 38

4-(3,4-Methylenedioxyphenoxy)benzaldehyde semicarbazone as anticonvulsant

The ability of 4-(3,4-methylenedioxyphenoxy)benzaldehyde semicarbazone to block maximal electroshock-induced seizures (MES) was determined by the following procedure.

Seizures were induced by application of current (50 mA, 60 pulses/sec, 0.8 msec pulse width, 1 sec duration, D.C.) using a Ugo Basile ECT device (model 7801). Mice were restrained by gripping the loose skin on their dorsal surface and saline-coated corneal electrodes were held lightly against the two cornea. Current was applied and mice were observed for a period of up to 30 sec for the occurrence of a tonic hindlimb extensor response. A tonic seizure was defined as a hindlimb extension in excess of 90 degrees from plane of the body.

4-(3,4-Methylenedioxyphenoxy)benzaldehyde semicarbazone was administered orally to mice 30 min before the test procedure. The compound exhibited protection against MES with an ED₅₀ (the dose provided protection of 50% of animals) of 5.3 mg/kg.

Additional compounds of the present invention were further tested in vitro and in vivo and the results are presented in Table 3. The relative in vitro potency of these compounds were determined by their ability to inhibit human skeletal muscle Na⁺ channel subunit stable expressed in HEK-293 cells. The techniques employed for Na⁺ current recordings and analysis with the use of this cell line were similar to that described in example 36. These studies employ depolarizing prepulses of varying duration to allow drugs to bind, a brief (5 ms) repolarizing step to reprime unbound channels, followed by the test pulse (5 ms) to measure what proportion of channels are inhibited. The reduction in peak currents is then plotted as a function of prepulse duration and the time constant (τ) measured by monoexponential fit. A plot of $1/\tau$ as a function of antagonist concentration then allows the macroscopic binding rates of the antagonists to be calculated. The anticonvulsant activities of additional

compounds of the present invention were determined as described in example 38.
